

Systematic reviews of diagnostic test accuracy studies

McGill Summer Institute, Montreal June 2017

Karen R Steingart, MD, MPH
Cochrane Infectious Diseases Group
Liverpool School of Tropical Medicine

karen.steingart@gmail.com

Declarations of Interest

- Editor, Cochrane Infectious Diseases Group and Cochrane Diagnostic Test Accuracy Editorial Team
- No financial disclosures

Overview

- Systematic reviews (DTA systematic reviews): what, why, and how
 - Formulate a review question, PICO
 - Describe quality assessment of DTA studies
 - Describe methods for analyzing data, including meta-analysis
 - Interpret results
-
- DTA = diagnostic test accuracy

A systematic review starts with a **clearly formulated question** and uses **systematic** and **explicit methods** to identify, select, and **critically appraise relevant research**, and to **collect** and **analyse** data from the studies that are included in the review

Egg slide adapted from Madhu Pai

A meta-analysis is the use of statistical techniques in a systematic review to integrate the results of included studies and analyse data from the studies that are included in the review.

Not all systematic reviews include a meta-analysis.

Why undertake a systematic review?

- **It is surely a great criticism of our profession that we have not organized a critical summary, by specialty and subspecialty, adapted periodically, of all relevant randomised controlled trials”**

- Archie L Cochrane, 1979 ‘Medicines for the year 2000’ London. Office for Health Economics. p1-11

Professor Archibald Leman
Cochrane, CBE FRCP FFCM, (1909-
1988)

The Ascent of Evidence (and the exhaustion of Man)

fig.1

fig.2

fig.3

fig.4

- The growing amount of information is challenging to manage
- Decision makers need to integrate critical pieces of information
- Systematic reviews are an efficient scientific technique

Systematic reviews of diagnostic test accuracy studies - terminology

- Index test(s) - new test
- Target condition - is a particular disease that the index test is intended to identify
- Reference standard (gold  standard) - an agreed-upon, accurate method for identifying patients who have the target condition

Diagnostic test accuracy - definition

- Diagnosis asks, “does this person have this disease (more generally, this target condition) at this point in time?”
- Diagnostic test accuracy refers to the ability of a test to distinguish between patients with disease and those without disease

Reference standard - a few comments

- The accuracy of an index test cannot be measured without a reference standard
- There should be general agreement that the reference standard is more accurate than the index test
- There may be more than one reference standard
- The reference standard may comprise several pieces of information
- The most accurate reference standard may not be feasible or ethical

Diagnostic test accuracy – what are we measuring?

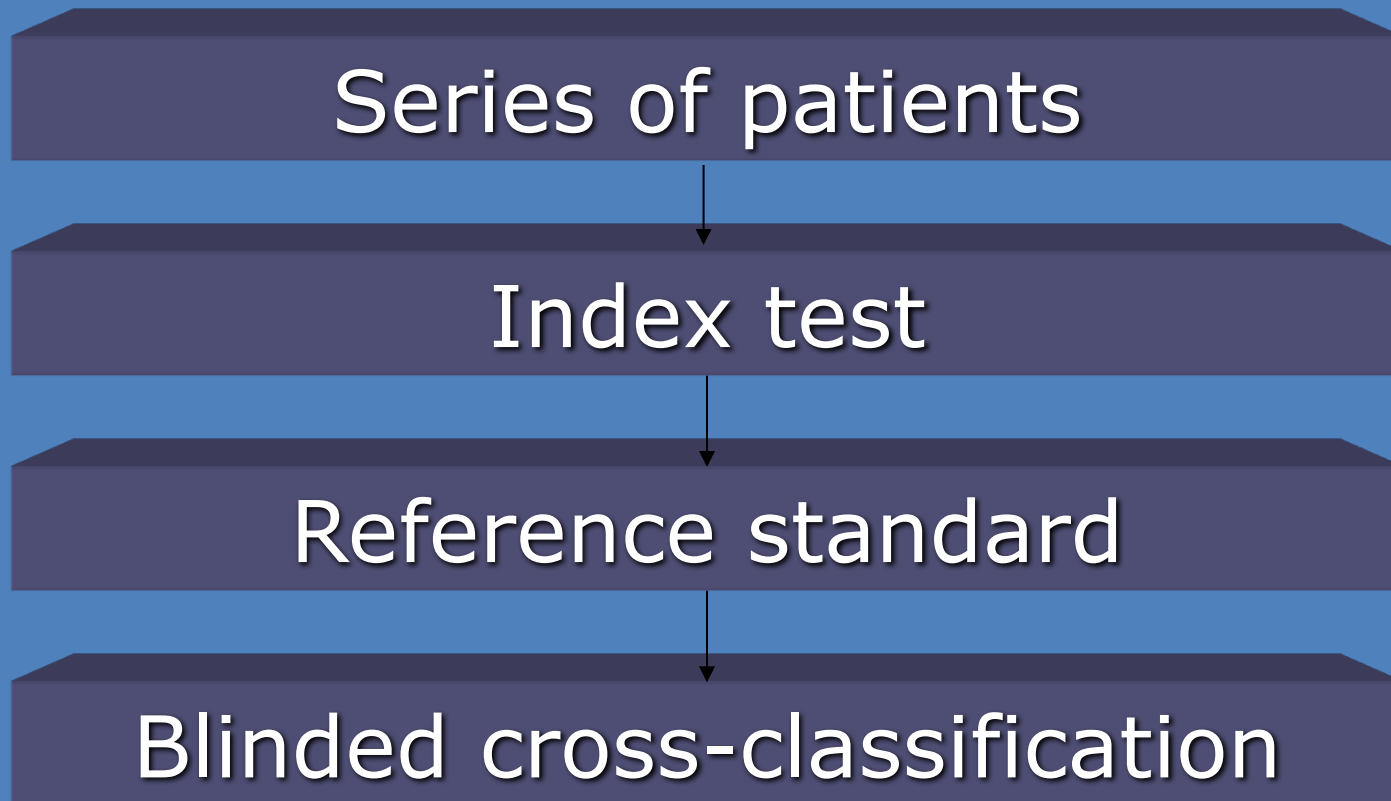

- Determine agreement between the results of the index test and the reference standard
 - Usually estimate sensitivity and specificity
 - Requires a 2×2 table

| | |
|-------------------|-------------------|
| True positive | False positive |
| False negative | True negative |

2x2 Table - sensitivity and specificity

| | | Disease (Reference standard) | | |
|------------|---|---------------------------------|-----------------------------|-------------|
| | | + | - | |
| Index test | + | True Positive | False Positive | |
| | - | False Negative | True Negative | |
| | | TP+FN | FP+TN | TP+FP+FN+TN |
| | | Sensitivity $TP/(TP+FN)$ | Specificity $TN/(TN+FP)$ | |

Diagnostic accuracy cross-sectional study design

Tests do not make patients better

Diagnostic accuracy \neq patient outcome

Image:

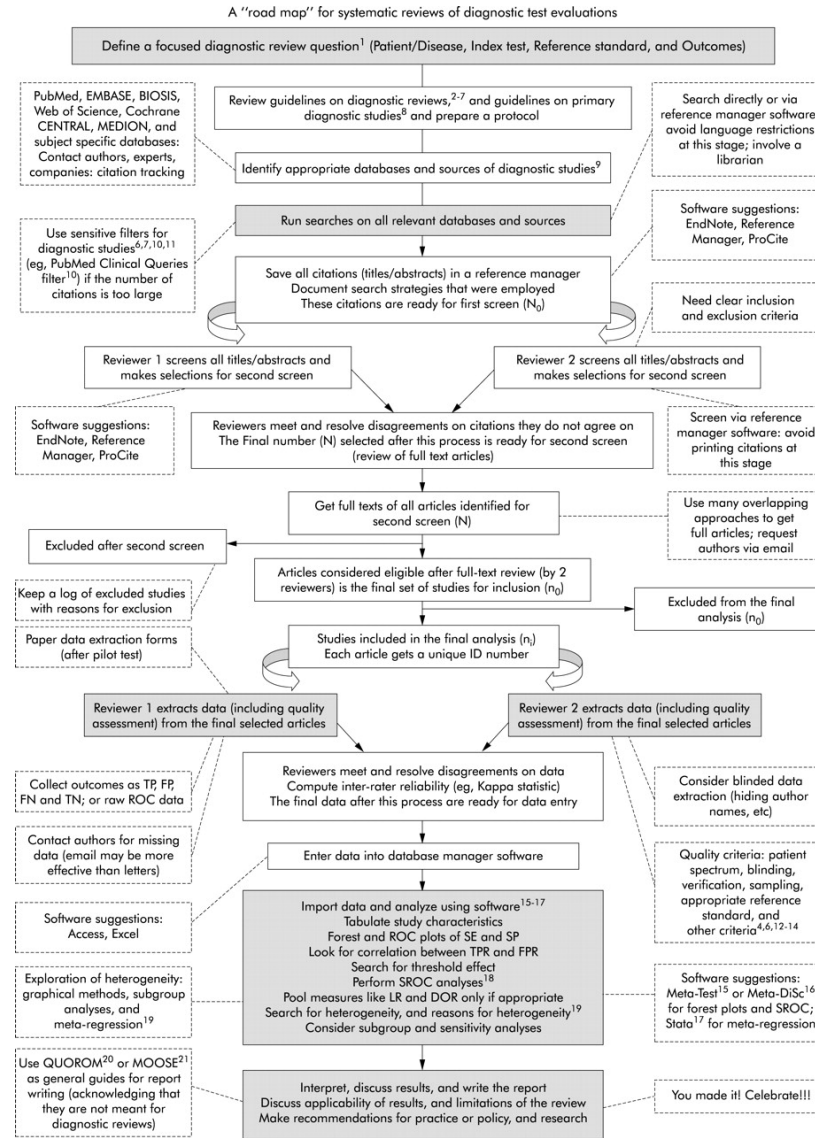

http://www.lung.ca/tb/images/full_archiv

Table 1| Attributes of the test-treatment pathway that affect patient health

| Pathway component and mechanism | Definition |
|--------------------------------------|---|
| (1) Diagnostic test delivered | |
| Timing of test | Speed with which a test is performed within the management strategy |
| Feasibility | Completion of test process. Reasons for non-completion are: patient acceptability (patient's refusal to have test), test was contraindicated (clinical reason not to administer test), and technical failure (ability of diagnostic equipment to produce data) |
| Test process | Patients' interaction with test procedure, potentially causing physical or psychological harms or benefits |
| (2) Test result produced | |
| Interpretability | Degree to which test data can be used to inform a diagnostic classification |
| Accuracy | Ability of a test to distinguish between patients who have disease and those who do not |
| Timing of results | Speed with which test results are available |
| (3) Diagnosis made | |
| Timing of diagnosis | Speed with which a diagnostic decision is made |
| Diagnostic yield | Degree to which the test contributes to a patient diagnosis in any form, including: provision of a definitive diagnosis, confirmation of a suspected diagnosis, ruling out a working diagnosis, and distinguishing between alternative diagnoses with different treatment implications. Diagnostic yield is different from accuracy because it also incorporates any other information used by a doctor to make a diagnosis (such as previous test results) |
| Diagnostic confidence | Degree of confidence that doctors and patients have in the validity or applicability of a test result |
| (4) Management decided | |
| Therapeutic yield | Degree to which diagnostic decisions affect treatment plans |
| Therapeutic confidence | Certainty with which doctors and patients pursue a course of treatment |
| (5) Treatment implemented | |
| Timing of treatment | Speed with which patients receive treatment |
| Treatment efficacy | Ability of the treatment intervention to improve patient outcomes |
| Adherence | Extent to which patients participate in the management plan, as advised by their doctor, to attain therapeutic goal |

Road map for diagnostic accuracy reviews

Pai M et al. Systematic reviews of diagnostic test evaluations: what's behind the scenes? Evid Based Med 2004;9:101-103

10 steps in performing a systematic review of diagnostic test accuracy studies

1. Define the review question and selection criteria
2. Write a protocol (plan the methods)
3. Search for studies
4. Apply selection criteria
5. Collect the data
6. Assess methodological quality
7. Analyze the data
8. Interpret results
9. Draw conclusions
10. Improve and update the review

**Define the review question and selection
(inclusion and exclusion) criteria**

Begin with a well-framed question - 1

- Participants
- Index test(s)

The index test was Alere Determine™ TB LAM Ag test. We evaluated the test at two different cut-off values for positivity (grade 1 and grade 2) based on the original manufacturer reference card.

- (Comparator test)
- Outcomes are usually sensitivity (true positives and false negatives) and specificity (false positives and true negatives)

Begin with a well-framed question - 2

- How do the participants present?
- What is the purpose of the test (such as screening, diagnosis, prognosis, monitoring)?
- What is the role of the new test (replacement, triage, add-on, combination with other tests?)

Role of tests

- Replacement: new test replaces existing test
- Triage: new test goes before existing test and only patients with a particular result go on to receive further testing
- Add-on: new test follows existing test
- Parallel: new test is used in combination with existing test(s)

Most situations are replacement

Why would you want to replace an existing test with a new test?

- More accurate
- More rapid
- Less invasive
- Technically easier to do
- Easier to interpret
- Other: storage, type of specimen, environment, infection control

PICO for systematic review of diagnostic test accuracy

- Participants
- Index test(s)
- Purpose of test
- Role of testing
- Target condition
- Reference standard
- Comparator (may or may not be included)
- Outcomes (usually sensitivity and specificity)

Lateral flow urine lipoarabinomannan assay for detecting active tuberculosis in HIV-positive adults

Professor Stephen Lawn

Urine lateral-flow lipoarabinomannan (LF-LAM)

Background - 1

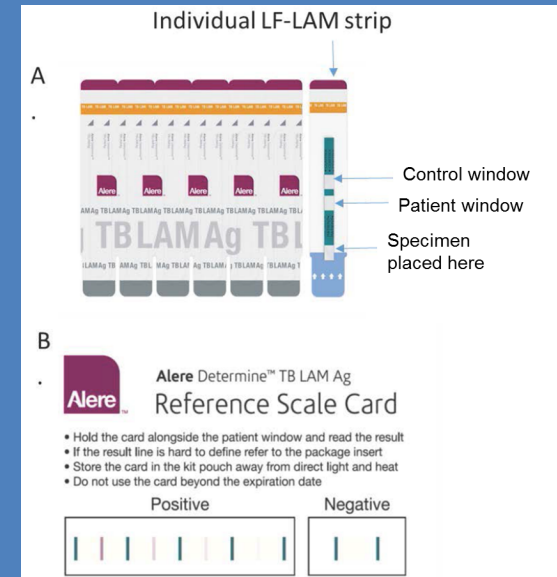

- LAM: 17.5 kilodalton structural component of mycobacterial cell walls
- Detectable in urine of patients with TB
- Meta-analysis of ELISA-LAM*
 - Increased sensitivity in HIV-positive compared with HIV-negative patients
 - Pooled sensitivity 56% (40-71%)
 - Pooled specificity 95% (77-99%)
 - Higher sensitivity with more severe immunosuppression

*Minion et al. ERJ 2011; Image: Se-Ho Park and Albert Bendelac. Nature 406, 788-792

LF-LAM Background – 2

- Urine LF-LAM is a new diagnostic test that may overcome limitations of other approaches
 - Point of care, lateral flow format
 - Fast (< 20 minutes)
 - No equipment needed
 - Low cost (~\$3.50)
 - Accuracy has varied across published studies

Where's PICO?

Objectives

- To assess the accuracy of LF-LAM for the diagnosis of active TB disease in HIV-positive adults who have signs and symptoms suggestive of TB (TB diagnosis)
- To assess the accuracy of LF-LAM as a screening test for active TB disease in HIV-positive adults irrespective of signs and symptoms suggestive of TB (TB screening)

Secondary objectives

- To compare diagnostic accuracy of LF-LAM and existing tests, sputum smear microscopy or sputum Xpert® MTB/RIF, as well as determine the diagnostic accuracy of LF-LAM when added to existing tests
- To investigate heterogeneity of test accuracy in the included studies (CD4 count and clinical setting)

Selection criteria - 1

- We included randomized controlled trials, cross-sectional studies, and cohort studies that determined LF-LAM accuracy for TB against a microbiological reference standard (culture or nucleic acid amplification test from any body site)
- We included abstracts with sufficient data
- We excluded case-control studies

Selection criteria - 2

- Participants were HIV positive adults
- We required studies to diagnose TB using at least one of the following two reference standards
 - Microbiological reference standard
 - Composite reference standard with (1) a positive culture, or (2) a positive NAAT, or (3) a positive smear, or (4) a clinical decision to start TB treatment

PICO for LF-LAM ?

- Participants =
- Presentation =
- Index test(s) =
- Purpose of test =
- Role of testing =
- Target condition =
- Reference standard =
- Comparator =
- Outcomes =

The medical literature can be compared to a jungle. It is fast growing, full of deadwood, sprinkled with hidden treasure and infested with spiders and snakes. Morgan. Can Med Assoc J, 134, Jan 15, 1986

Assess methodological quality (bias and applicability)

Beware the creeping cracks of bias

Evidence is mounting that research is riddled with systematic errors. Left unchecked, this could erode public trust, warns [Daniel Sarewitz](#).

09 May 2012

Alarming cracks are starting to penetrate deep into the scientific edifice. They threaten the status of science and its value to society. And they cannot be blamed on the usual suspects — inadequate funding, misconduct, political interference, an illiterate public. Their cause is bias, and the threat they pose goes to the heart of research.

[Recent](#) [Read](#) [Commented](#) [Emailed](#)

Nothing will corrode public trust more than a creeping awareness that scientists are unable to live up to the standards that they have set for themselves.

What is bias?

- Bias is **any process** at **any stage** of inference tending to produce **results** that **differ systematically** from the **true** values. *Murphy EA. The logic of medicine 1976*
- This is the tendency of some (poor) study designs **systematically** to produce results that are **better** (rarely if ever worse) than those with a robust design. Bias for diagnostic tests works in different ways to bias in trials of treatment. *Bandolier*

Three key sources of bias in diagnostic studies

1. Inclusion of right spectrum of patients
2. Verification of patients
 - choice of reference standard
 - complete verification
3. Independent interpretation of index test and reference standard results (blinding)

Quality Assessment of Diagnostic Accuracy Studies, QUADAS-2

- Domain list
 - patient selection
 - index test
 - reference standard
 - flow and timing
- Signalling questions are used for judgments of risk of bias
- First three domains are also assessed for applicability

QUADAS-2: A Revised Tool for the Quality Assessment of Diagnostic Accuracy Studies

Penny F. Whiting, PhD; Anne W.S. Rutjes, PhD; Marie E. Westwood, PhD; Susan Mallett, PhD; Jonathan J. Deeks, PhD; Johannes B. Reitsma, MD, PhD; Mariska M.G. Leeflang, PhD; Jonathan A.C. Sterne, PhD; Patrick M.M. Bossuyt, PhD; and the QUADAS-2 Group*

Are you concerned about risk of bias?

| | <u>Risk of Bias</u> | | | | <u>Applicability Concerns</u> | | |
|----------------|---------------------|------------|--------------------|-----------------|-------------------------------|------------|--------------------|
| | Patient Selection | Index Test | Reference Standard | Flow and Timing | Patient Selection | Index Test | Reference Standard |
| Andrews 2014 | + | + | - | + | + | + | + |
| Drain 2014c | - | + | - | + | + | + | + |
| Lawn 2014a | + | + | + | + | + | + | + |
| Nakiyingi 2014 | + | + | + | + | + | + | + |

| Peter 2015 | - | + | - | + | + | + | + |

| | | |
|--|---|---|
|  High |  Unclear |  Low |
|--|---|---|

Domain: reference standard

- **Could the reference standard, its conduct, or its interpretation have introduced bias?**
- **Signalling question 1: is the reference standard likely to correctly classify the target condition?**
- Due to the difficulties in diagnosing HIV-associated TB, it is recommended that multiple cultures from sputum and other specimens be evaluated.

Analyze the data

Statistical analysis and data synthesis

- Calculate estimates of sensitivity and specificity and 95% confidence intervals for individual studies
- Visually examine results of individual studies
- Calculate summary (pooled) accuracy estimates using recommended methods for meta-analysis
- Investigate possible reasons for heterogeneity

RevMan

Review Manager (RevMan) is the software used for preparing and maintaining Cochrane Reviews.

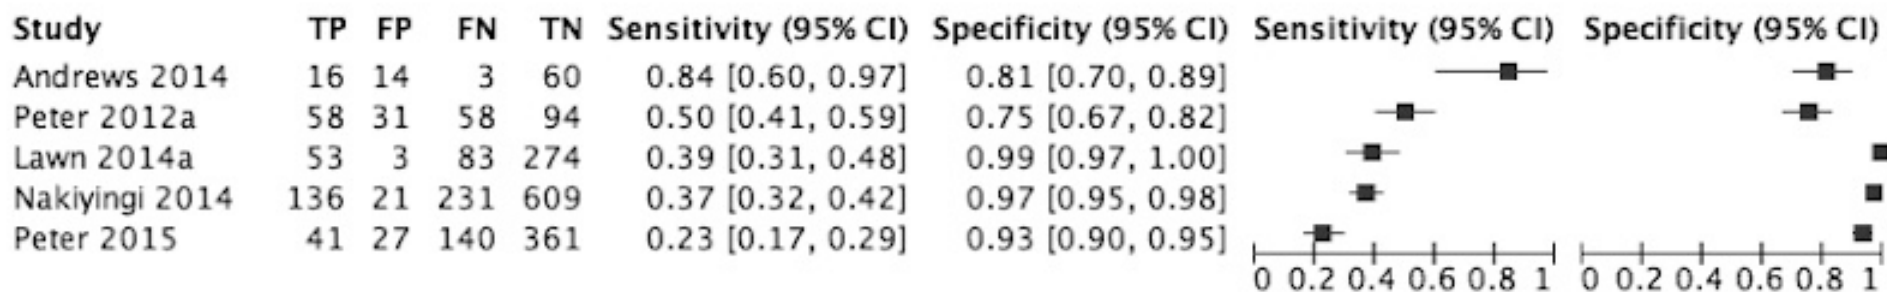

You can use **RevMan** for protocols and full reviews. It is most useful when you have formulated the question for the review, and allows you to prepare the text, build the tables showing the characteristics of studies and the comparisons in the review, and add study data. It can perform meta-analyses and present the results graphically.

Together with **Archie**, RevMan forms the Cochrane Information Management System (IMS), which is designed to enable contributors to the Cochrane Collaboration to meet the demands of producing high quality systematic reviews of the evidence of the effects of healthcare and deliver these for publication in **The Cochrane Library** and elsewhere.

<http://tech.cochrane.org/revman>

Forest plots of urine LAM sensitivity and specificity for TB diagnosis measured against a microbiological reference standard. The studies are ordered by decreasing sensitivity

TP = True Positive; FP = False Positive; FN = False Negative; TN = True Negative

Meta-analysis of diagnostic test accuracy

- Calculate the diagnostic accuracy of a test
- Compare the diagnostic accuracy of two or more tests
- Investigate the variability of results between studies (heterogeneity is to be expected)

How is a meta-analysis performed?

- The bivariate model
 - gives average sensitivity and specificity
 - use when studies report a *common threshold* for a positive result
- Hierarchical summary ROC curve
 - gives a summary ROC curve
 - use when studies report *several different thresholds*
- Both models use random effects

Meta-analysis with STATA

<http://methods.cochrane.org/sdt/software-meta-analysis-dta-studies>

Heterogeneity

- Refers to variation in results among studies
- May be caused by variation in
 - test thresholds (unique to meta-analyses of diagnostic tests)
 - prevalence of disease
 - patient spectrum
 - study quality
 - chance
 - unexplained

Visual inspection, do the confidence intervals overlap?

HIV positive

Heterogeneity, sensitivity and specificity of urine LAM for TB diagnosis stratified by CD4 count

When would you not do a meta-analysis?

*It has been said that a fellow with one leg frozen
in ice and the other leg in boiling water is
comfortable - on average.*

JM Yancey. Am J Surg. 1990;159:553-559.

Interpret results and draw conclusions

Summary of Findings Table - 1

- **Question:** what is the diagnostic accuracy of LF-LAM for diagnosing TB in adults living with HIV?
- **Participants:** HIV-positive adults with symptoms of TB
- **Index test:** LF-LAM
- **Role:** a replacement test or test in combination with sputum smear microscopy or sputum Xpert® MTB/RIF
- **Reference standard:** microbiological (mainly mycobacterial culture)

Summary of Findings Table - 2

- **Studies:** cross-sectional
- **Setting:** inpatient and outpatient
- **Limitations:** the main limitations of the review were the use of a lower quality reference standard in most included studies, and the small number of studies and participants included in the analyses
- **Pooled sensitivity:** 45% (95% CrI: 29 to 63);
pooled specificity: 92% (95% CrI: 80 to 97)

Summary of Findings Table - 3

| Test result | Number of results per 1000 patients tested (95% CrI) | | Number of participants (studies) | Quality of the Evidence (GRADE) |
|--|--|------------------|----------------------------------|--|
| | Prevalence 10% | Prevalence 30% | | |
| True positives (patients with tuberculosis) | 45 (29 to 63) | 135 (87 to 189) | 819 (5) | ⊕⊕⊕○ Moderate ¹ <u>,2,3</u> |
| False negatives (patients incorrectly classified as not having tuberculosis) | 55 (37 to 71) | 165 (111 to 213) | | |
| True negatives (patients without tuberculosis) | 828 (720 to 873) | 644 (560 to 679) | 1494 (5) | ⊕⊕○○ Low ^{2,4,5} <u></u> |
| False positives (patients incorrectly classified as having tuberculosis) | 72 (27 to 180) | 56 (21 to 140) | | |

Pooled sensitivity: 45% (29, 63)

Pooled specificity: 92% (80, 97)

Do you have confidence in the results, why or why not?

Pooled sensitivity: 45% (29, 63)

Pooled specificity: 92% (80, 97)

- Completeness of evidence?
- Accuracy of the reference standard?
- Quality and quality of reporting of included studies?
- Applicability of studies?

Completeness of evidence?

- This data set involved comprehensive searching and correspondence with experts in the field and the test manufacturer to identify additional studies, as well as repeated correspondence with study authors to obtain additional and unpublished data.
- The search strategy included studies published in all languages.
- We acknowledge that we may have missed some studies despite the comprehensive search.

Accuracy of the reference standard?

- HIV-positive TB patients may have pulmonary TB, extrapulmonary TB, or both pulmonary and extrapulmonary TB.
- Due to the difficulties in diagnosing HIV-associated TB, it is recommended that multiple cultures from sputum and other specimen types be evaluated.
- We therefore considered a reference standard using two or more specimen types to be of higher quality than a reference standard using one specimen type.

Quality, reporting, applicability

- Using GRADE approach, we judged the certainty of evidence for accuracy of LF-LAM for TB diagnosis to be low. This means that our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect
- Studies were fairly well reported, though we corresponded with almost all study authors for additional data
- We had low concern about the applicability of the included studies to our review question

RESEARCH

Open Access

A qualitative study into the difficulties experienced by healthcare decision makers when reading a Cochrane diagnostic test accuracy review

Zhivko Zhelev^{1*}, Ruth Garside^{2†} and Christopher Hyde^{1†}

- The most common error was to misinterpret the role of the reference standard as a comparator
- Participants could not recall definitions for sensitivity and specificity
- The Summary of Findings format was understood

In summary

- Express all components of the review question (PICO and more)
- Heterogeneity is to be expected in meta-analyses of diagnostic test accuracy; investigate the reasons for heterogeneity
- The Summary of Findings Table is useful for interpretation because it brings together the key elements of a review's findings
